

'Pricing under Rough Volatility Models' Lab Report

Artemy Sazonov, Andrei Petrov

Abstract

In the present paper we investigate the roughness of the Russian stock market. In order to do this, we study the behavior of the Zumbach effect in real market data and non-rough stochastic volatility model Monte-Carlo simulations. After that we study the RFSV model and we obtain the estimation of the Hurst parameter for the major Russian corporations. Furthermore, we investigate the sample normalized variation statistic and see that roughness could vary depending on estimation of volatility.

Introduction

One of the most famous models of mathematical finance was introduced by F. Black and M. Sholes in 1973's article [BS73], and a similar model for forward prices introduced in 1976 by F. Black in [Bla76]. Later there were invented some local volatility models, and stochastic volatility models (Heston, Hull and White, SVI, SABR etc.), but they still were not a perfect fit for pricing, even when first LSVMs were introduced.

Fractional Brownian motions were employed in volatility modelling by F. Comte and E. Renault in [CR98]. Their model (called FSV) used a fractional Brownian motion with Hurst parameter $H > 0.5$ to model volatility as a long-memory process i.e. one where autocorrelation decays slowly, which used to be a widely accepted stylized fact. They thus introduced the class of fractional stochastic volatility models.

In 2014, J. Gatheral, T. Jaisson, and M. Rosenbaum showed in [GJR14] that for major American indices Hurst parameter estimations are consistently less than 0.5, They called the corresponding model (FSV, $H < 0.5$) a rough fractional stochastic volatility model (RFSV) to emphasise that the volatility is indeed rough.

However, their approach requires the use of a model, therefore, it is not perfect still. In 2022, R. Cont and P. Das [CD22] proposed a method of estimating the roughness of an asset without the need of a model, which can be used to find statistical evidence that volatility is rough even without RFSV.

In the present paper we show that the Hurst parameters of the major Russia-originated assets (stocks and depositary receipts of Russian corporations) are less than 0.5 under RFSV, i.e. Comte and Renault's basic FSV model is not working well for the Russian stock markets, therefore, RFSV should be used instead.

Chapter 1

Basic Theoretical Aspects

1.1 Realized volatility

Consider a stochastic volatility model

$$dS_t = \mu_t S_t dt + \sigma_t S_t dW_t, \quad (1.1.1)$$

where S_t is an asset price process, and σ_t is a stochastic volatility process representing a so-called *spot volatility*. Spot volatility, in fact, is not observable in the market, therefore, we should estimate it somehow.

Definition 1.1.1. The *realized variance* of a price process S over time interval $[t, t + \delta]$ sampled along the time partition π^n is defined as

$$RV_{t,t+\delta}(\pi^n) = \sum_{\pi^n \cap [t,t+\delta]} \left(\log S_{t_{i+1}^n} - \log S_{t_i^n} \right)^2, \quad (1.1.2)$$

and *realized volatility* is defined as

$$RV_{t,t+\delta}(\pi^n) = \sqrt{\sum_{\pi^n \cap [t,t+\delta]} \left(\log S_{t_{i+1}^n} - \log S_{t_i^n} \right)^2}. \quad (1.1.3)$$

As pointed out in [Tha], realized volatility has some limitations:

1. The volume of data used influences the end results during the calculation of realized volatility. At least 20 observations are statistically required to calculate a valid value of realized volatility. Therefore, realized volatility is better used to measure longer-term price risk in the market (~ 1 month or more).
2. Realized volatility calculations are directionless. i.e., it factors in upward and downward trends in price movements.
3. It is assumed that asset prices reflect all available information while measuring volatility.

Definition 1.1.2. Let S satisfy (1.1.1). Then the integrated variance is defined as

$$IVar_t = \int_0^t \sigma_s^2 ds. \quad (1.1.4)$$

It has been shown many times (e.g. [BS02]) and mentioned in [CD22] that the realized variance converges in probability to the integrated variance as sampling frequency increases for all assets satisfying the equation (3.1.1) (i.e. stochastic volatility models).

Proposition 1.1.1. *As time partition scale of π^n tends to 0, $RV_{t,t+\delta}(\pi^n) \approx \sqrt{\delta}\sigma_t$, i.e. $RV_{t,t+\delta}/\sqrt{\delta}$ could be considered as a consistent estimator of the spot volatility.*

1.2 Fractional Stochastic Processes

Definition 1.2.1. The *fractional Brownian motion* $(W_t^H)_{t \in \mathbb{R}_+}$ with Hurst parameter $H \in (0, 1)$ is a Gaussian process with the following properties:

1. $W_0^H = 0$,
2. $\mathbb{E}[W_t^H] \equiv 0$,
3. $\mathbb{E}[W_s^H W_t^H] = \frac{1}{2}(t^{2H} + s^{2H} - |t - s|^{2H})$.

Definition 1.2.2. A stationary fOU process X_t is defined as the stationary solution of the stochastic differential equation

$$dX_t = \nu dW_t^H - \alpha(X_t - m)dt, \quad (1.2.1)$$

where $m \in \mathbb{R}$ and ν and α are positive parameters, see [CKM03].

Definition 1.2.3. Let us define $\Delta_h f(x) := f(x - h) - f(x)$ and let us define the modulus of continuity by

$$\omega_p^2(f, t) = \sup_{|h| \leq t} \|\Delta_h^2 f\|_p. \quad (1.2.2)$$

Let n be a non-negative integer and $s = n + \alpha$ with $\alpha \in (0, 1]$. The *Besov space* $B_{p,q}^s(\mathbb{R})$ contains all functions $f \in W^{n,p}(\mathbb{R})$ such that

$$\int_0^\infty \left| \frac{\omega_p^2(f^{(n)}, t)}{t^\alpha} \right|^q \frac{dt}{t} < \infty. \quad (1.2.3)$$

The Besov space $B_{p,q}^s(\mathbb{R})$ is a normed space with the standard norm defined as

$$\|f\|_{B_{p,q}^s(\mathbb{R})}^q = \|f\|_{W^{n,p}(\mathbb{R})}^q + \int_0^\infty \left| \frac{\omega_p^2(f^{(n)}, t)}{t^\alpha} \right|^q \frac{dt}{t}. \quad (1.2.4)$$

1.2.1 What is a long-memory process?

Definition 1.2.4. A process X_t is said to have a long memory, if

$$\sum_{k=0}^\infty \text{cov}[X_1, X_k - X_{k-1}] = \infty. \quad (1.2.5)$$

In particular, the fractional Brownian motion with $H > \frac{1}{2}$ is a long-memory process. Long-memory of the stochastic volatility process in stochastic volatility models framework used to be a widely-accepted stylized fact [BCD98; CR98; CR96; DGE93].

1.3 Normality Statistical Tests

In the following, x_i denotes a sample of n observations, g_1 and g_2 are the sample skewness and excess kurtosis, μ_j 's are the j -th sample central moments, and \bar{x} is the sample mean.

1.3.1 D'Agostino's K-squared test

The sample skewness and kurtosis are defined as

$$g_1 = \frac{m_3}{m_2^{3/2}} = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^3}{\left(\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^{3/2}}, \quad (1.3.1)$$

$$g_2 = \frac{m_4}{m_2^2} - 3 = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^4}{\left(\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^2} - 3. \quad (1.3.2)$$

Let

$$Z_1(g_1) = \delta \operatorname{asinh} \left(\frac{g_1}{\alpha \sqrt{\mu_2}} \right), \quad (1.3.3)$$

where constants α and δ are computed as

$$W^2 = \sqrt{2\gamma_2 + 4} - 1, \quad (1.3.4)$$

$$\delta = 1/\sqrt{\ln W}, \quad (1.3.5)$$

$$\alpha^2 = 2/(W^2 - 1), \quad (1.3.6)$$

and

$$Z_2(g_2) = \sqrt{\frac{9A}{2}} \left\{ 1 - \frac{2}{9A} - \left(\frac{1 - 2/A}{1 + \frac{g_2 - \mu_1}{\sqrt{\mu_2}} \sqrt{2/(A - 4)}} \right)^{1/3} \right\}, \quad (1.3.7)$$

where

$$A = 6 + \frac{8}{\gamma_1} \left(\frac{2}{\gamma_1} + \sqrt{1 + 4/\gamma_1^2} \right), \quad (1.3.8)$$

$$\mu_1(g_2) = -\frac{6}{n+1}, \quad (1.3.9)$$

$$\mu_2(g_2) = \frac{24n(n-2)(n-3)}{(n+1)^2(n+3)(n+5)}, \quad (1.3.10)$$

$$\gamma_1(g_2) \equiv \frac{\mu_3(g_2)}{\mu_2(g_2)^{3/2}} = \frac{6(n^2 - 5n + 2)}{(n+7)(n+9)} \sqrt{\frac{6(n+3)(n+5)}{n(n-2)(n-3)}}, \quad (1.3.11)$$

$$\gamma_2(g_2) \equiv \frac{\mu_4(g_2)}{\mu_2(g_2)^2} - 3 = \frac{36(15n^6 - 36n^5 - 628n^4 + 982n^3 + 5777n^2 - 6402n + 900)}{n(n-3)(n-2)(n+7)(n+9)(n+11)(n+13)}. \quad (1.3.12)$$

The analytical expressions for skewness and kurtosis (1.3.11) - (1.3.12) were derived by E. Pearson in [Pea31].

Definition 1.3.1. The *D'Agostino-Pearson* statistic is defined as

$$K^2 = Z_1(g_1)^2 + Z_2(g_2)^2 \quad (1.3.13)$$

H_0 : the sample is normally distributed.

Remark. The K^2 statistic is able to detect deviations from both skewness and kurtosis. If the null hypothesis is true, then the test statistic has the χ^2 distribution with 2 degrees of freedom.

1.3.2 Shapiro–Wilk test

Definition 1.3.2. The Shapiro–Wilk test statistic is defined as

$$W = \frac{\left(\sum_{i=1}^n a_i x_{(i)}\right)^2}{\sum_{i=1}^n (x_i - \bar{x})^2}, \quad (1.3.14)$$

where

$$(a_1, \dots, a_n) = \frac{m^T V^{-1}}{C}, \quad C = \|V^{-1}m\| = (m^T V^{-1} V^{-1} m)^{1/2},$$

and $m = (m_1, \dots, m_n)^T$ is a mean of order statistic from a normally distributed sample, V is the covariance matrix of those normal order statistics H_0 : the sample is normally distributed.

Remark. The W statistic has no distinguishable name, and the cutoff values are calculated numerically by Monte-Carlo simulation.

Chapter 2

Zumbach Effect Estimation

2.1 Empirical Effect

[El +18]

2.2 Monte-Carlo Simulation of Zumbach Effect

We conclude that Zumbach effect is an argument for the roughness of volatility. Therefore, we should consider a model of volatility driven by fractional Brownian motion.

Chapter 3

Rough Fractional Stochastic Volatility Model Estimation

3.1 Model description

In [GJR14] the authors considered the following model. Let there be a riskless asset $B_t \equiv 1$, and a risky asset, whose price S_t is defined by the following equations:

$$dS_t = \alpha S_t dt + \sigma_t S_t dW_t, \quad (3.1.1)$$

$$d \log \sigma_t = \alpha(m - \log \sigma_t) dt + \nu dW_t^H. \quad (3.1.2)$$

The risky asset is being traded in the market in numeraire prices. In our case, $B_t = 1$ RUB for stocks and 1 GBP for depositary receipts.

Definition 3.1.1. A model (3.1.1) – (3.1.2) is called a *Fractional Stochastic Volatility Model* (FSV). For a special case $H < 0.5$ the model is called a *Rough Fractional Stochastic Volatility Model* (RFSV) to emphasise a so-called roughness of the trajectories of the fBm. As a stylized fact we shall demand the stationarity off log-increments.

In [CKM03] an exact formula for the autocovariance function of the log-volatility in the RFSV model was derived:

$$\begin{aligned} \text{cov} [\log \sigma_t, \log \sigma_{t+\Delta}] &= \\ &= \frac{H(2H-1)\nu^2}{2\alpha^{2H}} \left(e^{-\alpha\Delta} \Gamma(2H-1) + e^{-\alpha\Delta} \int_0^{\alpha\Delta} \frac{e^u}{u^{2-2H}} du + e^{\alpha\Delta} \int_{\alpha\Delta}^{\infty} \frac{e^u}{u^{2-2H}} du \right). \end{aligned} \quad (3.1.3)$$

Let $m(q, \Delta, \pi^n)$ be a sample q -th absolute moment of $\log RV_{t+\Delta} - \log RV_t$:

$$m(q, \Delta, \pi^n) := \frac{1}{n} \sum_t |\log RV_{t+\Delta} - \log RV_t|^q, \quad (3.1.4)$$

i.e. $m(q, \Delta, \pi^n)$ is an empirical counterpart of $\mathbb{E}[|\log RV_\Delta - \log RV_0|^q]$. In this work we shall use the uniform partition of time scale with each step being equal to 15 minutes, so we omit the π^n notation and use $m(q, \Delta)$. Via the explicit formula for the covariance function of the log-volatility in the RFSV model (3.1.3), we can write a closed-form expression for a theoretical $m(2, \Delta)$:

$$m(2, \Delta) = 2 (\text{var} \log \sigma_t - \text{cov} [\log \sigma_t, \log \sigma_{t+\Delta}]). \quad (3.1.5)$$

3.2 Statistical Analysis

3.2.1 Data Preprocessing and Realized Volatility Estimation

In the present paper we used high-frequency data for three types of assets:

1. **Stocks:** Yandex, Sberbank, Gazprom, VTB, Moscow Exchange, Lukoil, and X5 Group;
2. **Depository reciepts:** Sberbank, Gazprom, VTB, and Lukoil;
3. **Funds:** AEX, AORD, BFX, BVSP, DJI, FCHI, FTMIB, FTSE, GDAXI, GSPTSE, HSI, IBEX, IXIC, KS11, KSE, MXX, N225, OMXC20, OMXHPI, OMXSPI, OSEAX, RUT, SMSI, SPX, SSEC, SSML.

Figure 3.1: YNDX RX Equity. Price and Realized Volatility

Realized volatility is estimated by 15 minute disjoint windows (i.e. $\hat{RV}(t)$ is a piecewise constant function). Using this approach for the estimation, we can be sure that our data is correlated in the least way possible. We observe in the Figure 3.1 that as the price decreases, the rolling mean of realized volatility generally increases.

3.2.2 Hurst Parameter Estimation

Main assumption: for some $s_q > 0$, $b_q > 0$ and $N = \lfloor \frac{T}{\Delta} \rfloor$ (number of RV estimations via disjoint windows)

$$N^{qs_q} m(q, \Delta) \xrightarrow{\Delta \rightarrow 0+} b_q. \quad (3.2.1)$$

Under additional technical conditions equation (3.2.1) is equivalent to that the volatility process belongs to the Besov smoothness space $B_{q,\infty}^{s_q}$ and for all $\tilde{s}_q > s_q$ does not belong to $B_{q,\infty}^{\tilde{s}_q}$ [Ros08].

Due to the similarities in the obtained results for all assets, we shall deeply analyze the Hurst parameter estimation only for the Yandex stocks (YNDX RX Equity). Plots for other equities could be found in the appendix, whereas the Hurst parameter estimations for them could be found in the Table 3.1. Further in the paper we assume $\Delta = 1, \dots, 40$. It has been shown that under stationarity assumptions and linearity of Figure 3.4 (left)

$$\mathbb{E}[|\log \sigma_{t+\Delta} - \log \sigma_t|^q] = K_q \Delta^{\zeta_q}, \quad (3.2.2)$$

and the s_q does not depend on q . In the Figure 3.4 (right) we can see that for $q = 0.6, 0.8$, and 1.0 the dots are very discrepant for $\log \Delta > 2.0$. However, we get a pretty decent linear fit for $q = 0.2$ and $q = 0.4$, therefore, the estimation on these two point would be the best one we can manage to extract. On the other hand, on ζ_q plot we observe a perfect linear fit for all q -s, therefore, H is its slope indeed. We note that the graphs for ζ_q are slightly concave, which correlates with

Figure 3.2: YNDX RX Equity. Plots for \hat{H}

[GJR14] results. They conclude that this effect takes place due to the finite statistical population size. It has been proven in [GJR14] that $\log \mathbb{E}[\sigma_t \sigma_{t+\Delta}]$ and $\log \text{cov}[\log \sigma_t, \log \sigma_{t+\Delta}]$ are linear in Δ^{2H} . And we indeed observe this behaviour in the majority of plots (especially for $\Delta < 20$, where we have enough data to work with). Numerical instability occurs when Δ is too large due to the lack of HF data.

NB. We did not manage to obtain more HF data (only 5 months of 1m-tick data), therefore my estimations are not precise and could not be used for further application.

In the figure 3.4 we can see that for $q = 0.6, 0.8$, and 1.0 the dots are very discrepant for $\log \Delta > 2.0$. However, we get a pretty decent linear fit for $q = 0.2$ and $q = 0.4$, therefore, the estimation on these two point would be the best one we can manage to extract. On the other hand, on ζ_q plot we observe a perfect linear fit for all q -s, therefore, H is its slope indeed.

We note that the graphs for ζ_q are slightly concave, which correlates with [GJR14] results. They conclude that this effect takes place due to the finite statistical population size.

3.2.3 Smoothing Effect Estimation

Smoothing effect is thoroughly discussed in the appendix of [GJR14].

Figure 3.3: YNDX RX Equity. Empirical counterpart of $\log \mathbb{E}[\sigma_t \sigma_{t+\Delta}]$ as a function of Δ^{2H} (left) and Empirical counterpart of $\log \text{cov}[\log \sigma_t, \log \sigma_{t+\Delta}]$ as a function of $\log \Delta$ (right)

Table 3.1: Hurst parameter estimations

Figure 3.5: YNDX RX Equity. Empirical counterpart of $\log \mathbb{E}[\sigma_t \sigma_{t+\Delta}]$ as a function of Δ^{2H} (left) and Empirical counterpart of $\log \text{Cov}[\sigma_t, \sigma_{t+\Delta}]$ as a function of $\log \Delta$ (right)

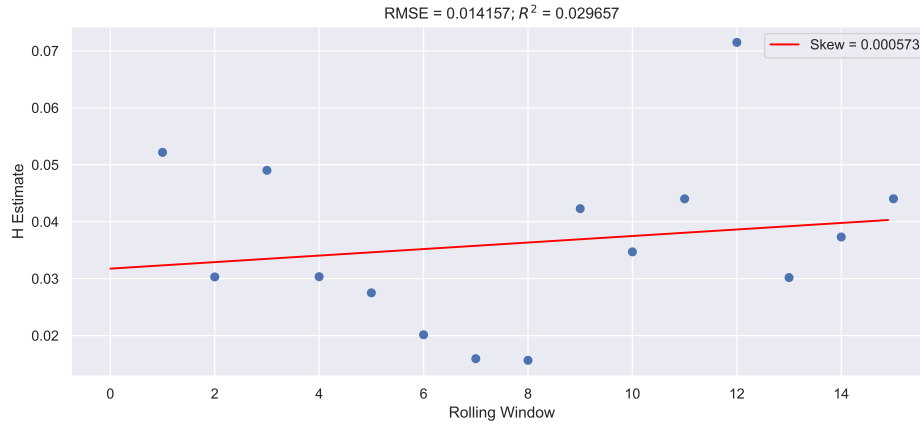

Figure 3.6: YNDX RX Equity. Smoothing Effect

We can clearly see that due to the positive slope of the plot 3.6, the hypothesis about increasing \hat{H} and decreasing $\hat{\alpha}$ as δ increases is to be accepted.

3.2.4 Tests for normality of volatility's log-increments

In order to test the normality of the log-increments of the realized volatility, we used the following tests:

1. Visual analysis of histograms: KDE vs normal fit vs empirical fit
2. Visual analysis of excessed kurtosis plot
3. D'Agostino's K Squared normality test
4. Shapiro-Wilk normality test

In [GJR14] the authors used **only** the visual analysis of the histograms, which, as we can now say, is not surprising due to the inadequacy of results for other numerical experiments.

Visual analysis of histograms and excessed kurtosis plot

1. KDE is the *kernel density estimator* of the data.
2. *Normal fit* $NF(\Delta)$ is the normal distribution fitted to the data with the same mean and variance.
3. *Empirical fit* $EF(\Delta)$ is the scaled normal distribution:
 - $EF(1)$ is said to be same as the $NF(1)$
 - $EF(\Delta)$ for $\Delta > 1$ is said to be a scaled $NF(1)$ by the factor of $\Delta^{\hat{H}}$ (by this we test the monofractal scaling property of normal distribution)

Looking at the figure 3.7, we may form a conclusion: *KDE* and *EF* are a decent normality approximations for $\Delta = 10, 20$. For others, we don't get a fancy picture: $KDE(1)$ and $KDE(5)$ have a large kurtosis (they are too 'peaky' for them to be normally distributed). Excessed kurtosis plot 3.8 confirms our visual conclusion for *KDE* and *EF* plots.

Statistical tests for normality

We fix the confidence level to be $\alpha = 0.05$.

NB. Both of these tests require the data to be independent, but we cannot guarantee this due to the dependence of fBm's increments. We do our best to analyse the population, but these two tests give us weak proof of normality due to possible correlations.

Looking at the tables with the results of Shapiro-Wilk and D'Agostino's K-Squared tests (tables ?? – ??), we can see that for the majority of lags and for the majority of the considered assets, both tests showed the result "Not normal", i.e. both tests rejected the null hypothesis.

The three possible explanations are:

1. The tests are correct and the data is not normally distributed or is correlated strongly.

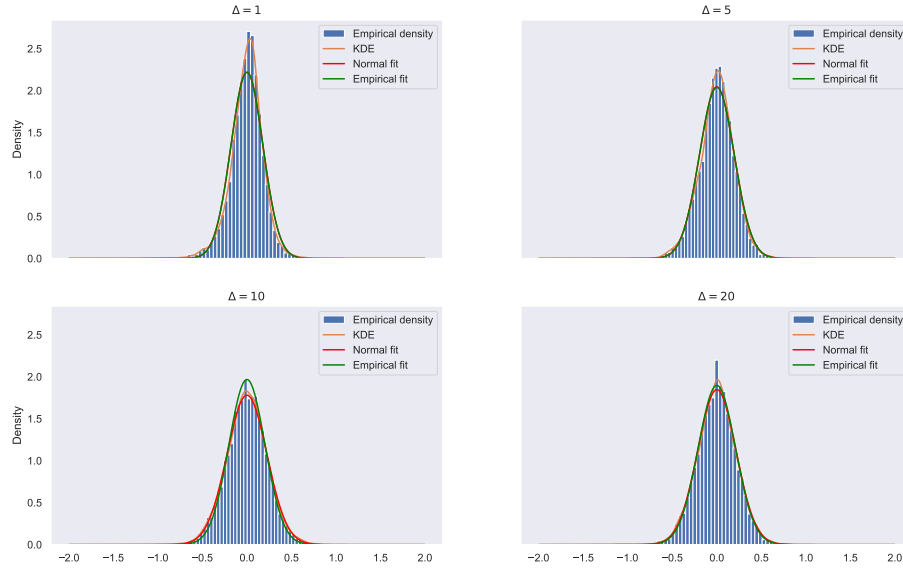

Figure 3.7: YNDX RX Equity. Empirical density of $\log \sigma_{t+\Delta} - \log \sigma_t$ for $\Delta = 1, 5, 10, 20$ days.

Figure 3.8: YNDX RX Equity. Excessed kurtosis κ as a function of Δ

2. The visual analysis of the histograms show that for many lags the KDE plot, the normal fit and the empirical fit are very similar, therefore, the distribution is normal, but the data is correlated strongly. The excessed kurtosis plot shows that the data is distributed very close to the normal distribution for $\Delta > 5$, and at its closest distance for $\Delta \in [10, 22]$.
3. We get a population sampling error (not enough data).

Chapter 4

Modelless Estimation of Roughness

4.1 Sample normalized variation as a measure of roughness

4.1.1 Theoretical parameters

Let us consider a sequence of partitions π^n of $[0, T]$ with $|\pi^n| := \max_{t_i^n \in \pi^n} (t_{i+1}^n - t_i^n) \rightarrow 0$.

Definition 4.1.1. A function $x \in C[0, T]$ is said to have the finite p -th variation along the sequence of partitions π^n if there exists a continuous increasing function $[x]_\pi^{(p)}$ such that for all subpartitions $\tilde{\pi}^n(t) = \pi^n \cap [0, t]$

$$\sum_{t_i^n \in \tilde{\pi}^n(t)} |x(t_{i+1}^n) - x(t_i^n)|^p \rightarrow [x]_\pi^{(p)}(t), \quad n \rightarrow \infty, \quad (4.1.1)$$

and the set of all functions having finite p -th variation along π we denote V_π^p .

Definition 4.1.2. The *variation index* of a path x is defined as $p^\pi(x) := \inf \{p \geq 1 : x \in V_\pi^p\}$, and the *roughness index* is defined as $H^\pi(x) := \frac{1}{p^\pi(x)}$.

It has been proven that for fBm with Hurst parameter H $p^\pi(W^H) = \frac{1}{H}$ and $H^\pi(W^H) = H$.

Definition 4.1.3. $x \in V_\pi^p$ is said to have p -th normalized variation if there exists such continuous function $w(x, p, \pi) : [0, T] \rightarrow \mathbb{R}$ that

$$\sum_{\tilde{\pi}^n(t)} \frac{|x(t_{i+1}^n) - x(t_i^n)|^p}{[x]_\pi^{(p)}(t_{i+1}^n) - [x]_\pi^{(p)}(t_i^n)} (t_{i+1}^n - t_i^n) \rightarrow w(x, p, \pi). \quad (4.1.2)$$

From Theorem 2.4 [CD22], it is known that the variation index must be found as a solution of

$$w(x, p, \pi) = t. \quad (4.1.3)$$

4.1.2 The W Statistic

4.2 Roughness estimation of Monte-Carlo simulations

4.2.1 Brownian and fractional Brownian motion

We shall test our method on those processes, whose roughness is well-known.

Figure 4.1: The W statistic illustration as a function of p

Brownian motion

We observe that the roughness index is equal to 0.4988, which is a pretty good approximation.

Fractional Brownian motion (Davies-Harte method)

We considered four Hurst parameters for simulation: 0.15, 0.35, 0.55, and 0.75. We used the Davies-Harte method of generating the fBm since this one is widely accepted as the most precise. We observe not the best approximations, but they are decent enough to be in $(\mu - \sigma, \mu + \sigma)$.

4.2.2 Heston stochastic volatility model

We observe that roughness estimations for instantaneous volatility and realized volatility significantly differ, which was described in the article for fOU processes.

4.3 Roughness estimation of real-market data

Let us estimate the roughness of real-market data. We are using the same Bloomberg data from Table 3.1 (but without indexes).

As we can see, modelless estimation of roughness differs from the Hurst parameter under RFSV (as Monte-Carlo simulations predicted).

Conclusion

Reproduced Hypotheses

We got acquainted with the fractional stochastic volatility models framework and studied the statistical properties of RFSV. We obtained roughness estimations for major Russian companies stocks and depositary receipts, and reproduced some effects described in [GJR14].

1. The Hurst exponent of the considered assets has the order of $1e - 1$ and is less than $\frac{1}{2}$.
2. The volatility of the considered assets **does not** have a property of long memory under fractional stochastic volatility models.
3. Visual analysis and normality tests for the log-increments of volatility shows that for $\Delta \in [10, 25]$ the normality of log-increments hypothesis holds.
4. The smoothing effect holds for the estimations of H and α (volatility of volatility under fOU). But **only** for VTBR LI Equity we got a negative slope of the smoothing effect. For other asset we got a nearly perfect linear fit and positive smoothing slopes.
